

Transverse momentum of charged particles at low Q^2 at HERA (H1)

Anastasia Grebenyuk

on behalf of the H1 collaboration

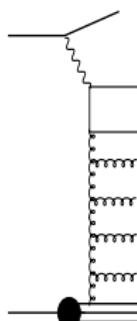

DIS 2010, Florence, Italy. April 2010

Outline

- Introduction and motivation
- Analysis details
- Results
- Summary

Evolution equations

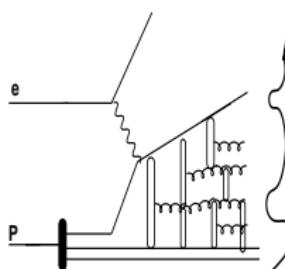

DGLAP

DGLAP

Strong ordering in
transverse momentum

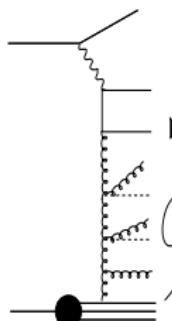

CDM (Color Dipole Model)

CDM = non-DGLAP

Random walk
in transverse momentum

CCFM

CCFM = non-DGLAP

Random walk
in transverse momentum

DGLAP model (RAPGAP)

$$Q_0^2 \ll k_{T1}^2 \ll \dots \ll k_{Tn}^2 \ll Q^2$$

DGLAP works when Q^2 is large, but x is not too small

beyond-DGLAP models (random walk in k_T)

- CDM (Color Dipole Model) (DJANGOH-CDM)
(not evolution equation, but gives BFKL-like final state)
works for small x and Q^2 is not large
- CCFM (CASCADE) $\xi_0 < \xi_1 < \dots < \xi_n < \Xi$
Valid for both, small and large x

HFS as an access to the dynamics of the cascade

$F_2(x, Q^2)$ has too little sensitivity to discriminate between DGLAP and beyond-DGLAP.
 Semi-inclusive measurements $ep \rightarrow e' hX$ are believed to possess higher discriminating power.

The observables for physics beyond DGLAP at HERA:

- Transverse energy flow
- Forward jets with $p_{T\text{jet}}^2 \sim Q^2$
- Transverse momentum spectra:

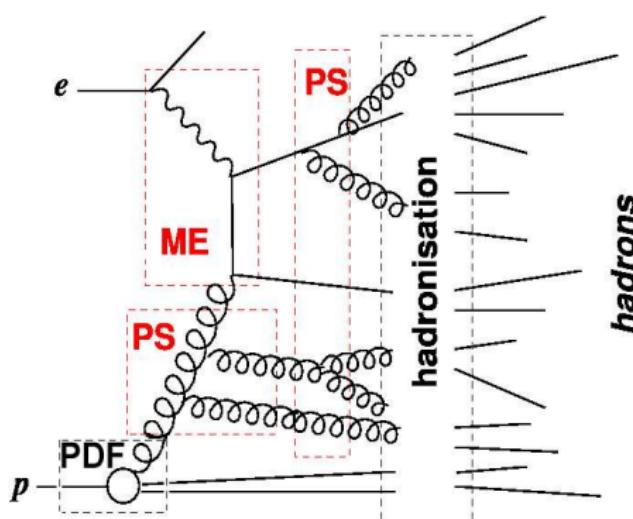

Hadrons at large p_T :

disfavoured by the strong p_T ordering → difference between different parton dynamics

Low p_T region:

hadronisation effects are expected to play a role.

Small sensitivity to different parton dynamic models.

Experimental setup and reconstruction

- HERA beam energies: $E_e = 27.6 \text{ GeV}$, $E_p = 920 \text{ GeV}$
- Data 2006e⁺: $L = 88.64 \text{ pb}^{-1}$

- Scattered electron*

Information from scattered electron (E'_e, θ'_e) is used to reconstruct the kinematics:

$$Q^2 = 4E_e E'_e \cos^2 \frac{\theta'_e}{2}$$

$$y_e = 1 - \frac{E_e}{E'_e} \sin^2 \frac{\theta'_e}{2}$$

In this analysis:

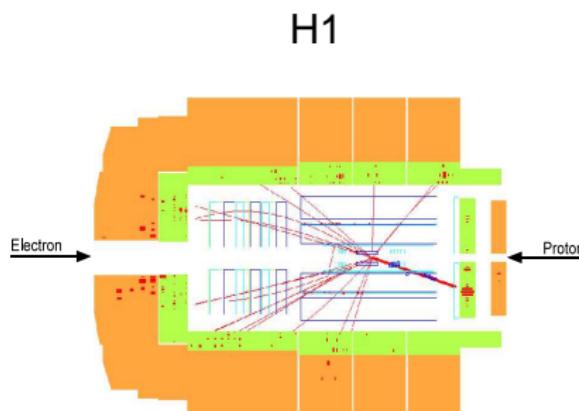

$$5 < Q^2 < 100 \text{ GeV}^2, 0.05 < y < 0.7$$

- For charged particles*

Only central tracks are analysed.

Track selection:

$$p_T > 0.15 \text{ GeV}, 20^\circ < \Theta < 155^\circ$$

Reference frames

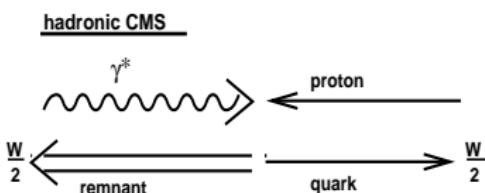

- Laboratory frame:

$$\eta = -\ln \tan(\frac{\theta}{2})$$

θ - with respect to proton direction

$\eta > 0 \Leftrightarrow$ proton direction

- Hadronic centre-mass system (HCM):

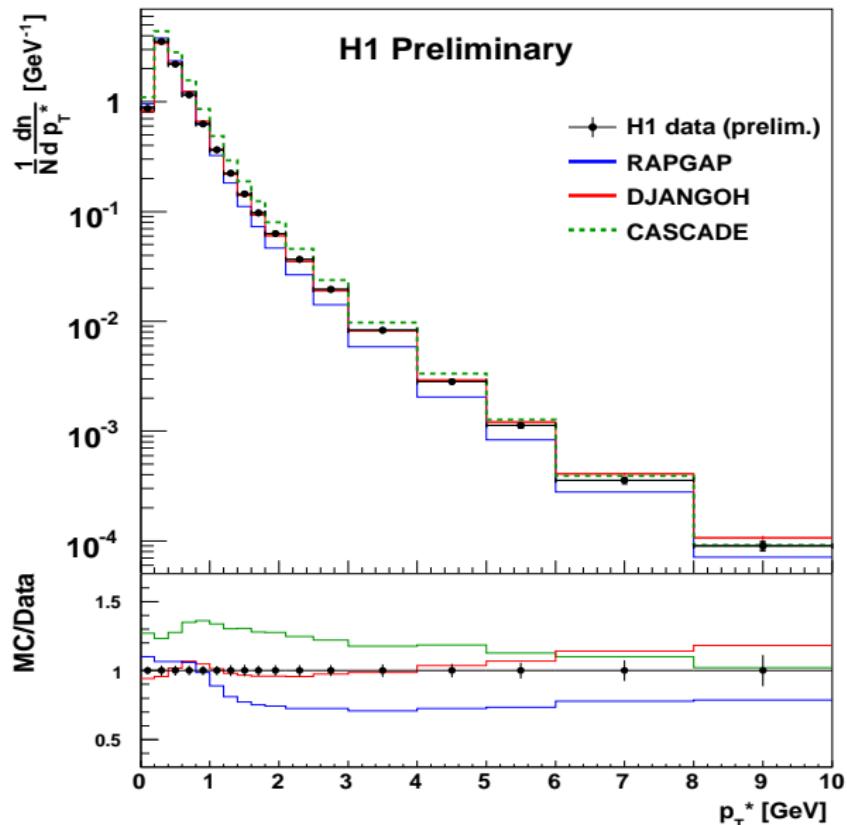

$$\eta^* = -\ln \tan(\frac{\theta^*}{2})$$

θ^* - with respect to virtual photon direction

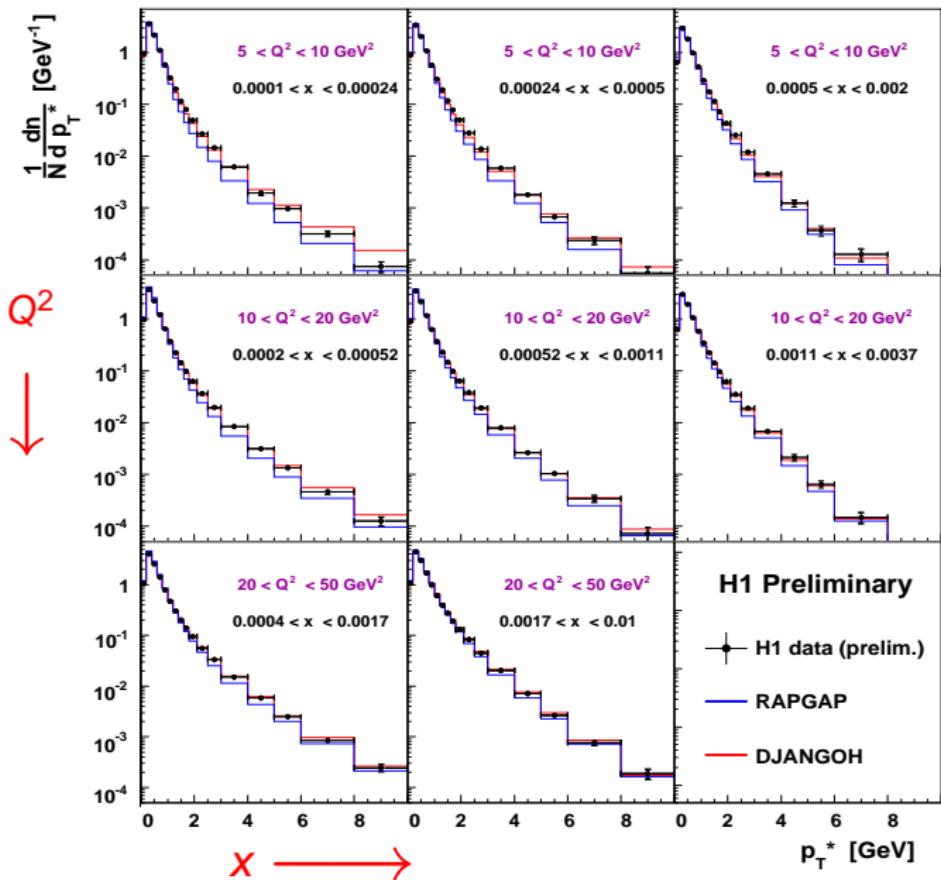

$\eta^* < 0 \Leftrightarrow$ proton direction

η^* region: $0 < \eta^* < 6$;

p_T^* distribution is studied in $1.5 < \eta^* < 2.5$ region

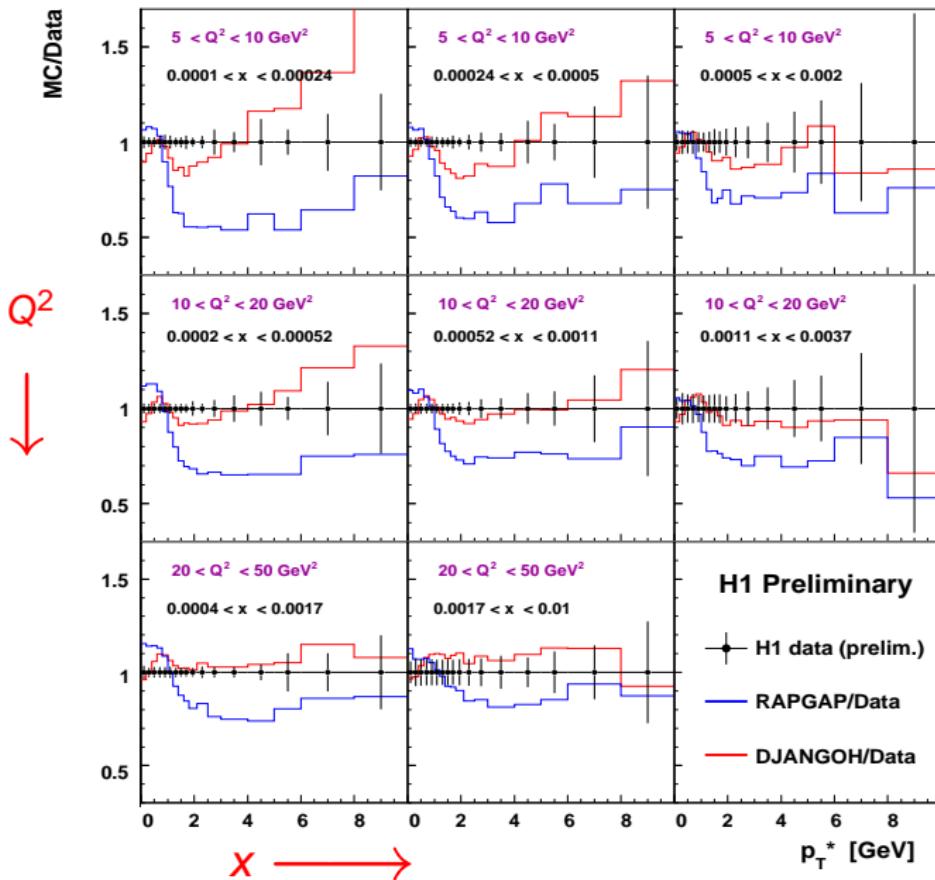

p_T^* spectra: DATA vs. DJANGOH/RAPGAP/CASCADE

- DJANGOH(CDM)
describes new data for
whole p_T^* spectra
- RAPGAP(DGLAP) is below
the data for $p_T^* > 1 \text{ GeV}$
- In contrast,
CASCADE(CCFM) is
systematically above the
data

p_T^* distribution in bins of (x , Q^2)

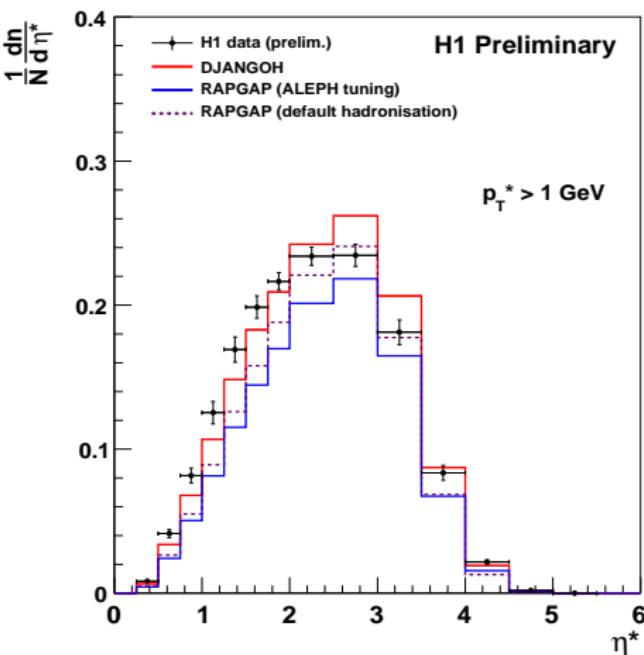

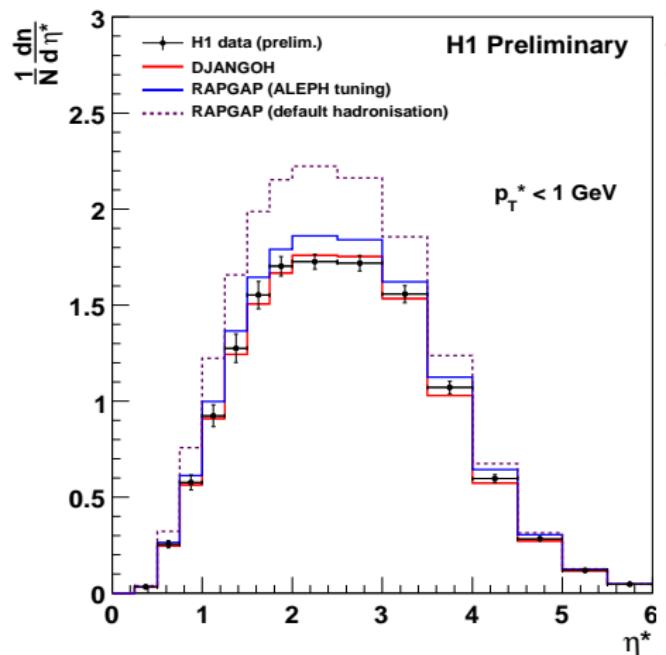

RAPGAP(DGLAP) is below the data at lowest x and Q^2 region

ratios of p_T^* distribution in bins of (x , Q^2)

Strongest
disagreement
between both models
and the data at high
 p_T^* at low Q^2 and
low x

H1 Preliminary

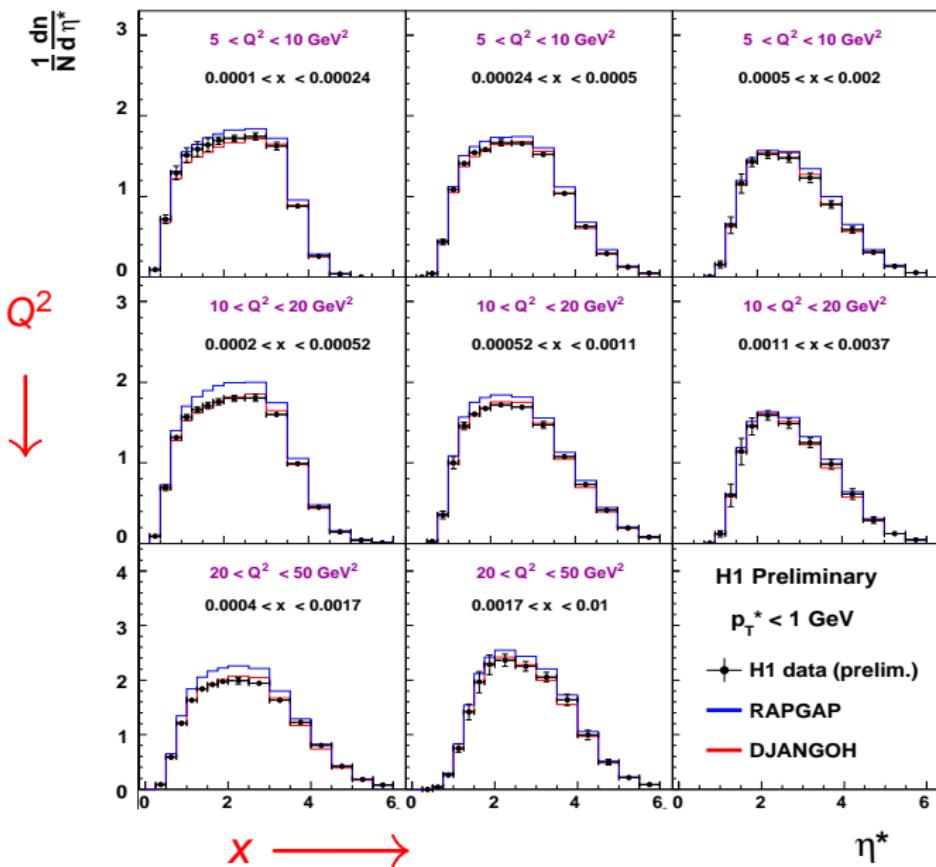

η^* - distributionsCharged particles with $p_T^* < 1$ GeV:Charged particles with $p_T^* > 1$ GeV:

Strong sensitivity to hadronisation parameters.

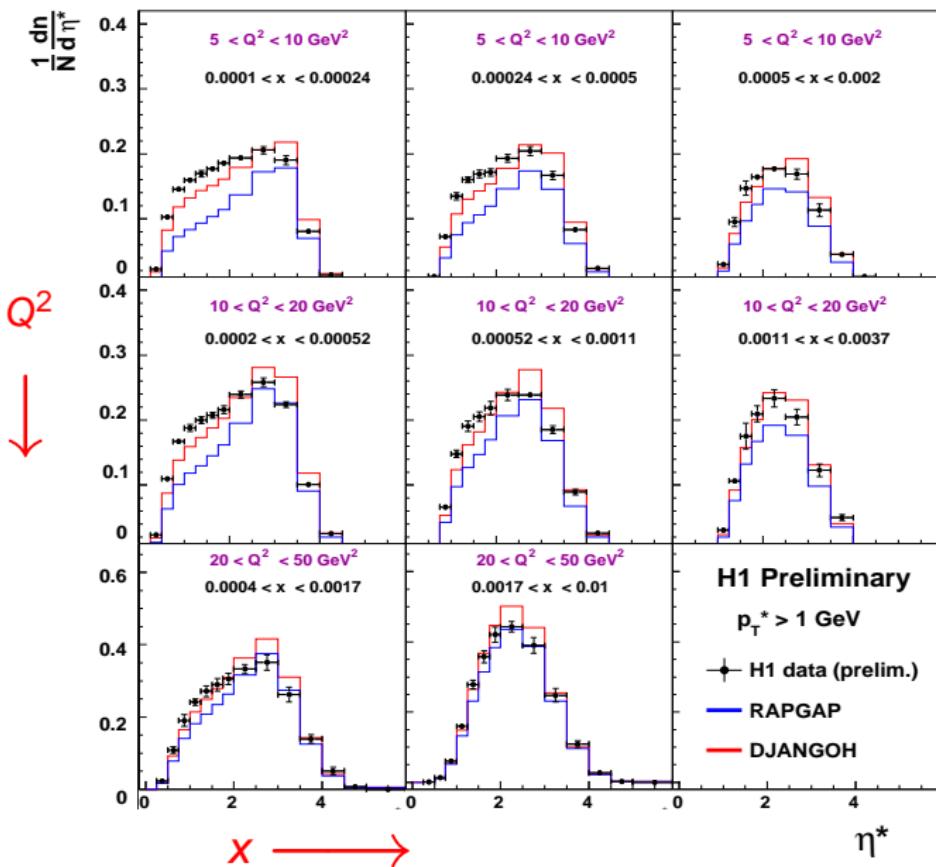

Weak sensitivity to different parton dynamics.

Strong sensitivity to different parton dynamics.

Weak sensitivity to hadronisation parameters.

η^* distribution in bins of (x, Q^2) for $p_T^* < 1 \text{ GeV}$ 

Both RAPGAP(DGLAP)
and DJANGOH(CDM)
provide reasonable
description of the data
for all (x, Q^2) -bins

η^* distribution in bins of (x, Q^2) for $p_T^* > 1 \text{ GeV}$;

RAPGAP(DGLAP) is below the data for almost all (x, Q^2) -bins (except last 2 bins). The difference is more pronounced in forward direction ($\eta^* < 2$)

Summary

- Transverse momenta and rapidity spectra were measured with H1 detector at HERA (2006 $e^+ p$ data)
 - Obtained distributions, overall and for various (x, Q^2) -regions, are used to discriminate DGLAP and beyond DGLAP dynamics
 - Low p_T^* region ($p_T^* < 1$ GeV):
 - Both RAPGAP(DGLAP) and DJANGOH(CDM) provide good description of the data for both p_T^* and η^* distributions
 - More studies needed for CASCADE
 - η^* distribution is sensitive to the fragmentation parameters
 - Hard p_T^* region ($p_T^* > 1$ GeV):
 - DJANGOH(CDM) is better than RAPGAP(DGLAP) in describing both, p_T^* and η^* measured spectra, especially at low x
- data are in favor of beyond DGLAP models
